## Chapter 9 - Multiple and Logistic Regression

Baby weights, Part I. (9.1, p. 350) The Child Health and Development Studies investigate a range of topics. One study considered all pregnancies between 1960 and 1967 among women in the Kaiser Foundation Health Plan in the San Francisco East Bay area. Here, we study the relationship between smoking and weight of the baby. The variable *smoke* is coded 1 if the mother is a smoker, and 0 if not. The summary table below shows the results of a linear regression model for predicting the average birth weight of babies, measured in ounces, based on the smoking status of the mother.

	Estimate	Std. Error	t value	$\Pr(> t )$
(Intercept)	123.05	0.65	189.60	0.0000
smoke	-8.94	1.03	-8.65	0.0000

The variability within the smokers and non-smokers are about equal and the distributions are symmetric. With these conditions satisfied, it is reasonable to apply the model. (Note that we don't need to check linearity since the predictor has only two levels.)

(a) Write the equation of the regression line.

$$baby \ \hat{w}eight = 123.05 - 8.94*smoker$$

(b) Interpret the slope in this context, and calculate the predicted birth weight of babies born to smoker and non-smoker mothers.

The average baby weight is 123.05 ounces if the mother is a non-smoker and 114.11 ounces if the mother is a smoker

(c) Is there a statistically significant relationship between the average birth weight and smoking?

Yes, the t value is high and the p value is low. The null hypothesis should be rejected.

Absenteeism, Part I. (9.4, p. 352) Researchers interested in the relationship between absenteeism from school and certain demographic characteristics of children collected data from 146 randomly sampled students in rural New South Wales, Australia, in a particular school year. Below are three observations from this data set.

	eth	sex	lrn	days
1	0	1	1	2
2	0	1	1	11
:	:	:	:	:
146	1	0	0	37

The summary table below shows the results of a linear regression model for predicting the average number of days absent based on ethnic background (eth: 0 - aboriginal, 1 - not aboriginal), sex (sex: 0 - female, 1 - male), and learner status (1rn: 0 - average learner, 1 - slow learner).

	Estimate	Std. Error	t value	Pr(> t )
(Intercept)	18.93	2.57	7.37	0.0000
$\operatorname{eth}$	-9.11	2.60	-3.51	0.0000
sex	3.10	2.64	1.18	0.2411
$\operatorname{lrn}$	2.15	2.65	0.81	0.4177

(a) Write the equation of the regression line.

$$days \ \hat{a}bsent = 18.93 - 9.11 * NotAboriginal + 3.1 * Male + 2.15 * SlowLearner$$

(b) Interpret each one of the slopes in this context.

Aborignals on average miss 9.11 more days. (All other things being equal) Males on average miss 3.1 more days. (All other things being equal) Slow Learners on average miss 2.15 more days. (All other things being equal)

(c) Calculate the residual for the first observation in the data set: a student who is aboriginal, male, a slow learner, and missed 2 days of school.

```
predicted<-18.93 - (9.11 * 0) + (3.1 * 1) + (2.15 * 1)
actual<-2
sprintf("The residual is %.3f", actual-predicted)</pre>
```

## [1] "The residual is -22.180"

(d) The variance of the residuals is 240.57, and the variance of the number of absent days for all students in the data set is 264.17. Calculate the  $R^2$  and the adjusted  $R^2$ . Note that there are 146 observations in the data set.

$$R^2 = \frac{Var(residuals)}{Var(observations)}$$

```
var_residuals<-240.57
var_observations<-264.17
n<-146
k<-3  # 3 variables each with 2 values

r_squared<-var_residuals/var_observations
adj_r_squared<-r_squared * (n-1)/(n-3-1)

sprintf("R squared = %.3f.  Adj R Squared = %.3f", r_squared, adj_r_squared)

## [1] "R squared = 0.911.  Adj R Squared = 0.930"</pre>
```

**Absenteeism, Part II.** (9.8, p. 357) Exercise above considers a model that predicts the number of days absent using three predictors: ethnic background (eth), gender (sex), and learner status (lrn). The table below shows the adjusted R-squared for the model as well as adjusted R-squared values for all models we evaluate in the first step of the backwards elimination process.

	Model	Adjusted $\mathbb{R}^2$
1	Full model	0.0701
2	No ethnicity	-0.0033
3	No sex	0.0676
4	No learner status	0.0723

Which, if any, variable should be removed from the model first?

Ethnicity. The Adjusted R squared is very low meaning the predictor (ethnicity) doesnt influence the response (absenteeism) very much.

Challenger disaster, Part I. (9.16, p. 380) On January 28, 1986, a routine launch was anticipated for the Challenger space shuttle. Seventy-three seconds into the flight, disaster happened: the shuttle broke apart, killing all seven crew members on board. An investigation into the cause of the disaster focused on a critical seal called an O-ring, and it is believed that damage to these O-rings during a shuttle launch may be related to the ambient temperature during the launch. The table below summarizes observational data on O-rings for 23 shuttle missions, where the mission order is based on the temperature at the time of the launch. Temp gives the temperature in Fahrenheit, Damaged represents the number of damaged O-rings, and Undamaged represents the number of O-rings that were not damaged.

1	2	3	4	5	6	7	8	9	10	11	12
53	57	58	63	66	67	67	67	68	69	70	70
5	1	1	1	0	0	0	0	0	0	1	0
1	5	5	5	6	6	6	6	6	6	5	6
13	14	15	16	17	18	19	20	21	22	23	
70	70	72	73	75	75	76	76	78	79	81	
1	0	0	0	0	1	0	0	0	0	0	
5	6	6	6	6	5	6	6	6	6	6	
-	53 5 1 13 70 1	53 57 5 1 1 5 13 14 70 70 1 0	53 57 58 5 1 1 1 5 5 13 14 15 70 70 72 1 0 0	53 57 58 63 5 1 1 1 1 5 5 5 13 14 15 16 70 70 72 73 1 0 0 0	53 57 58 63 66 5 1 1 1 0 1 5 5 5 6 13 14 15 16 17 70 70 72 73 75 1 0 0 0 0	53     57     58     63     66     67       5     1     1     1     0     0       1     5     5     5     6     6    13 14 15 16 17 18 70 70 70 72 73 75 75 1 0 0 0 0 1	53     57     58     63     66     67     67       5     1     1     1     0     0     0       1     5     5     5     6     6     6       13     14     15     16     17     18     19       70     70     72     73     75     75     76       1     0     0     0     0     1     0	53     57     58     63     66     67     67     67       5     1     1     1     0     0     0     0       1     5     5     5     6     6     6     6       13     14     15     16     17     18     19     20       70     70     72     73     75     75     76     76       1     0     0     0     0     1     0     0	53     57     58     63     66     67     67     67     68       5     1     1     1     0     0     0     0     0       1     5     5     5     6     6     6     6     6       13     14     15     16     17     18     19     20     21       70     70     72     73     75     75     76     76     78       1     0     0     0     0     1     0     0     0	53     57     58     63     66     67     67     67     68     69       5     1     1     1     0     0     0     0     0     0       1     5     5     5     6     6     6     6     6     6       8     6     6     6     6     6     6     6     6       9     70     70     72     73     75     75     76     76     78     79       1     0     0     0     0     1     0     0     0     0	53     57     58     63     66     67     67     67     68     69     70       5     1     1     1     0     0     0     0     0     0     1       1     5     5     5     6     6     6     6     6     6     6     5       13     14     15     16     17     18     19     20     21     22     23       70     70     72     73     75     75     76     76     78     79     81       1     0     0     0     0     0     0     0     0     0

(a) Each column of the table above represents a different shuttle mission. Examine these data and describe what you observe with respect to the relationship between temperatures and damaged O-rings.

When the temperature fell below 60, the O Ring damage increased.

(b) Failures have been coded as 1 for a damaged O-ring and 0 for an undamaged O-ring, and a logistic regression model was fit to these data. A summary of this model is given below. Describe the key components of this summary table in words.

	Estimate	Std. Error	z value	$\Pr(> z )$
(Intercept)	11.6630	3.2963	3.54	0.0004
Temperature	-0.2162	0.0532	-4.07	0.0000

This model provides a meaningful probability of o-ring damage in the temperature range of 50 to 60, i.e. at 52 degrees:

$$P(damage\ at\ 52\ degrees) = 11.663 - .2162 * 52 = .74$$

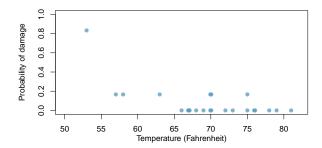

(c) Write out the logistic model using the point estimates of the model parameters.

$$Y_i = log(\frac{\hat{p}}{1-\hat{p}}) = 11.663 - .2162 * temperature$$

(d) Based on the model, do you think concerns regarding O-rings are justified? Explain.

Yes. The low pvalues suggest a high level of confidence that as temperatures get lower and lower, risk of catastrophe increases.

Challenger disaster, Part II. (9.18, p. 381) Exercise above introduced us to O-rings that were identified as a plausible explanation for the breakup of the Challenger space shuttle 73 seconds into takeoff in 1986. The investigation found that the ambient temperature at the time of the shuttle launch was closely related to the damage of O-rings, which are a critical component of the shuttle. See this earlier exercise if you would like to browse the original data.

(a) The data provided in the previous exercise are shown in the plot. The logistic model fit to these data may be written as

$$\log\left(\frac{\hat{p}}{1-\hat{p}}\right) = 11.6630 - 0.2162 \times Temperature$$

where  $\hat{p}$  is the model-estimated probability that an O-ring will become damaged. Use the model to calculate the probability that an O-ring will become damaged at each of the following ambient temperatures: 51, 53, and 55 degrees Fahrenheit. The model-estimated probabilities for several additional ambient temperatures are provided below, where subscripts indicate the temperature:

$$\hat{p}_{57} = 0.341$$
  $\hat{p}_{59} = 0.251$   $\hat{p}_{61} = 0.179$   $\hat{p}_{63} = 0.124$   $\hat{p}_{65} = 0.084$   $\hat{p}_{67} = 0.056$   $\hat{p}_{69} = 0.037$   $\hat{p}_{71} = 0.024$ 

```
temp<-c(51,53,55)
# temp<-c(59,61,63)
le_results<-11.663-(0.2162*temp) # result of linear equation
exp_x<-exp(le_results)
p_hats<-round(exp_x/(1+exp_x),4)
results.df<-cbind(temp,p_hats)

```

Table 1: Logistic Probability of Damage

temp	p_hats
51	0.6540
53	0.5509
55	0.4432

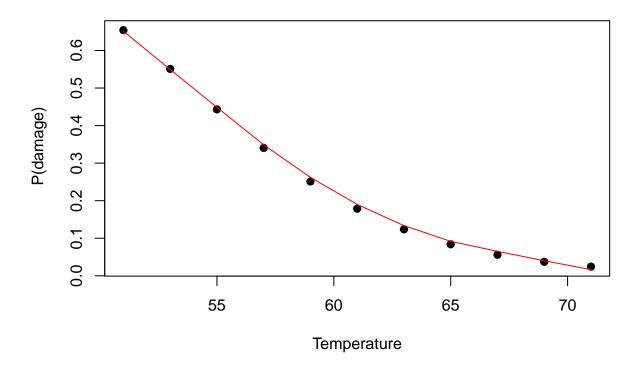

(b) Add the model-estimated probabilities from part~(a) on the plot, then connect these dots using a smooth curve to represent the model-estimated probabilities.

```
temp<-c(51,53,55,57,59,61,63,65,67,69,71)
le_results<-11.663-(0.2162*temp)  # result of linear equation
exp_x<-exp(le_results)
p_hats<-round(exp_x/(1+exp_x),4)

results.df<-cbind(temp,p_hats)

plot(temp,p_hats, main="Logistic Probability O-Ring Damage", xlab="Temperature", ylab=" P(damage)", pch
# lowess() adds more granular regression (curved line)
lines(lowess(temp,p_hats), col="red")</pre>
```

## **Logistic Probability O-Ring Damage**

(c) Describe any concerns you may have regarding applying logistic regression in this application, and note any assumptions that are required to accept the model's validity.

The sample size was too small and I would think there are other factors and more scientific analysis needs to be done.
